## THESIS

## WATER ACCOUNTING PLUS (WA+) FOR THE TONLE SAP LAKE BASIN USING SATELLITE-DERIVED DATA AND WEAP MODEL

A Thesis Submitted in Partial Fulfillment of the Requirements for the Degree of Master of Engineering (Irrigation Engineering)

Graduate School, Kasetsart University
Academic Year 2018

PHANIT MAB : Water Accounting Plus (WA+) for the Tonle Sap Lake Basin using Satellite-Derived Data and WEAP Model. Master of Engineering (Irrigation Engineering), Major Field: Irrigation Engineering, Department of Irrigation Engineering. Thesis Advisor: Associate Professor Ekasit Kositsakulchai, Ph.D. Academic Year 2018

In this study, water balance analysis in term of water accounting plus was assessed by satellite-derived data. The main objectives of this study were to evaluate the satellite-derived data for estimating the components of water accounting plus (WA+), to analyze water balance in the Tonle Sap Lake basin by WEAP model, and to conduct the WA+ under the current situation. Water balance analysis showed that the Mekong River is the key water source of the Tonle Sap Lake. It represented more than half of total inflow, while the watershed streamflow contributed about one-third of total inflow. According to the resource base sheet of annual WA+, inflow from rainfall represented around $78 \%$ of the net inflow. Surface inflow from the Mekong River also showed significant component of around $22 \%$. The depleted water from evapotranspiration was more than half, while the surface outflow was only $35 \%$. For the seasonal WA+, the highest depleted water occurred during the wet season around $76 \%$. Only $24 \%$ was released to downstream. Moreover, the storage of the Tonle Sap Lake showed also an important role in the available water during the dry season. The evapotranspiration sheet provided the water depletion from different land-use categories. The highest water depletion was in Utilized Land Use class, it takes place more than half. However, this land use type, most of the water depletion occurred from wetlands. Modified Land Use also demonstrated a high one around $29 \%$ which happened in the agricultural land. To maintain this amount of water, it should pay attention to agricultural water use by improving land and water productivity. These would be a help to decrease water consumption and increase crop production. The main sources for reducing water depletion is to reduce soil evaporation.

## ACKNOWLEDGEMENTS

This thesis was supported by the Kasetsart University Scholarships for ASEAN for Commemoration of the 60th Birthday Anniversary of Professor Dr. Her Royal Highness Princess Chulabhorn Mahidol. Moreover, I would also like to show my gratitude to the WEAP model and Google Earth Engine (GEE) developers for providing a license during this research.

Firstly, I would like to express my sincere gratitude to my advisor Dr. Ekasit Kositsakulchai, for the continuous support of my study and related courses, for his patience, motivation, and immense knowledge. His guidance helped me in all the time of research and writing of this thesis.

Secondly, my sincere thanks also go to my co-advisor Dr. Chuphan Chompuchan, GIS and remote sensing courses who provided me many documents to learn, and taught and guided me through the concepts of GIS and remote sensing. Without his precious support, it would not be possible to conduct this thesis.

Many thanks to professors, Department of Irrigation Engineering, Faculty of Engineering, Kasetsart University at Kamphaeng Saen Campus, who provided me an opportunity to join their classes as a master's degree student. I am very grateful to whom that always concern.

I would like to thank Dr. Ketvara Sittichok and Dr. Areeya Rittima for all guidance through the final examination, their discussion, ideas, and feedbacks have been absolutely invaluable for me.

Besides my advisor, co-advisor and professors, I would like to thank my family, friends, who supported me for their insightful comments and encouragement.

# WATER ACCOUNTING PLUS (WA+) FOR THE TONLE SAP LAKE BASIN USING SATELLITE-DERIVED DATA AND WEAP MODEL 

## INTRODUCTION

The Mekong River flows through to six countries namely Cambodia, China, Lao PDR, Myanmar, Thailand and Vietnam (Goh, 2017). The river originates in the Tangelo mountain range in Qinghai province of China (Phua, 2011). The part of the Mekong River Basin within China and the eastern end of Myanmar is known as the Upper Mekong River Basin (UMRB) (Wassmann et al., 2004) and lower part is known as the Lower Mekong River Basin (LMRB) within Cambodia, Lao, Myanmar, Thailand and Vietnam (Pink, 2016). The LMRB covers about $70 \%$ of the basin and is the most significant region both economically and environmentally (Promkotra, 2014), including the Tonle Sap Lake basin. Out of total catchment area of 795,000 $\mathrm{km}^{2}$, around $25 \%$ lies in the Lao PDR, $23 \%$ in Thailand, $21 \%$ in Yunnan (China), $20 \%$ in Cambodia, $8 \%$ in Vietnam and only $3 \%$ is part of the Myanmar (Eastham et al., 2008)

The Tonle Sap ecosystem in Cambodia is a major component of the Mekong basin, consisting of the Tonle Sap Lake, the Tonle Sap River and their surrounding floodplains. The Tonle Sap Lake is linked to the Mekong River through the 100 km long Tonle Sap River tributary (Welcomme, 1985). When water levels in the Mekong rise above a threshold level, usually in late May - early June, flow in the Tonle Sap River is reversed and Mekong water is pushed into the Tonle Sap River and Lake. During the wet season, the volume of the lake increases from about $1.3 \mathrm{~km}^{3}$ to $50-80$ $\mathrm{km}^{3}$ depending on the flood intensity, and its surface area increases from $2,500 \mathrm{~km}^{2}$ to $10,000-15,000 \mathrm{~km}^{2}$ (Kummu, 2003).

The lake is the largest freshwater body in Southeast Asia. The lake is reported to be very productive (MRC, 2002; Rainboth, 1996). The lake functions as a natural flood retention for the Mekong system during the dry season (November-April), when approximately half of the discharge to the Mekong Delta in Vietnam originates from the lake (Fujii et al., 2003). The ecosystem is driven by a flood pulse regime, supporting a fishery and aquaculture that provides approximately up to $80 \%$ of the protein consumption of Cambodia (Ahmed et al., 1998). Due to its extraordinary role the Tonle Sap Lake can be regarded as the 'Heart of the Mekong'; without it the Mekong River and its aquatic life would not flourish as it does today. The role of the Tonle Sap for Cambodia is even greater. It has been approximated that as many as half of the country's population benefits directly or indirectly from the lake's resources (Bonheur, 2001). Over 3.6 million Cambodian people depend on this lake in living and derive their livelihoods directly from its natural resources (ADB, 2005).

Over the last 50 years, the world situation has changed from an abundance of water to a situation of water scarcity. Over 1.2 billion people live in basins where water demand is reaching, or has exceeded limits of sustainable use (Gleick, 2000). Population growth, changing diets, and economic growth, are some of the main causes of increased water use, which has resulted in competition for water, closed basins (a basin where all available water is depleted), overexploited groundwater resources, degraded land, reduced ecosystem services and anthropologically induced droughts(Karimi et al., 2013). Water resources have been less effective in managing water in this relatively new era of scarcity (Alcamo et al., 2007).

Water accounting integrates the fields of hydrology, water and environmental management, water allocations, reporting and communication. It facilitates identification of central problems in river basins, constraints and opportunities for improved climate resilience. It assists with decisions regarding carbon sequestration and safeguarding sufficient water resources for a good quality life, also during periods of prolonged drought(Karimi et al., 2013). Water accounting is described in this context below.

Water balance is a key determinant for the distribution and productivity (Churkina et al., 1999) of terrestrial vegetation around the globe. In turn, the composition and distribution of plant communities are of fundamental importance for evapotranspiration and runoff generation (Dunn and Mackay, 1995). Water balance analysis can be used to: identify and quantify water inflows and outflows. It also identifies changes in stocks of water; quantifies components of the water balance. (Batchelor et al., 2017).

Water resource management models are effective tools for addressing water shortages. This is because water supply and demand simulations can support decision processes for regional water resource planning (Andreu et al., 1996). Techniques for estimating water balance range from very simple methods, such as lumped models and field-experiment techniques, to highly complex computer-based models that can calculate water balance at various temporal (e.g., hourly, daily, monthly, and yearly) and spatial scales(Xu and Singh, 1998; Zhang et al., 2002). Selection of an appropriate technique depends on the objectives of the study and availability of data.

In this case, water accounting and water resources modelling system can be more effective tools to identify the water resources management. It can use the spatial information from the satellite-derived data.

In developing country likes Cambodia, the available data from the monitoring stations is the critical problem in order to study the water balance analysis. Rainfall, evapotranspiration (ET), are absence for the whole study areas. Even where data available, the quality and temporal data are not good enough. It causes too difficult to evaluate the components of hydrological cycle of the basin. However, all these datasets must be assessed for the water balance analysis components. The lack of meteorological stations forces the researcher to retrieve datasets from other sources. Remote sensing is the appropriate method to obtain the free online datasets. Additionally, the Google Earth Engine (GEE) could allow us to get datasets quickly and easily with the reliable outputs. In this study, the GEE is a main platform application to request all input data.

## OBJECTIVES

In this study, it focused on the question: "How to conduct the assessment of water resources in an area with a limited data availability on Cambodia using satellitederived data?" The main objectives of this study were:

1. To evaluate the satellite-derived data for estimating the components of Water Accounting Plus (WA+).
2. To analyze water balance in Tonle Sap Lake basin by a water resource system model.
3. To conduct the WA+ analysis of Tonle Sap Basin under the current situation.

## SCOPE AND LIMITATION

In this work, the Water Accounting Plus (WA+) framework was selected in order to address the water resources situation in the Tonle Sap Lake watershed. The analysis was based on current surface water of the basin and selected annual and monthly time series data from 2000 to 2014. The Water Evaluation And Planning (WEAP) was used to calculate of the inter-connected water balance components in the basin.

## LITERATURE REVIEWS

## 1. Water Accounting

The journals and reporting on water accounting has been reviewed many times by various researchers who worked on this sector. Water accounting changed framework many time following as the weakness points of each tools. Several international organizations had developed new generation of water accounting frameworks such as, the United Nation (UN), the International Water Management Institute (IWMI) and the Australian government.

The United Nations Statistics Division has proposed a water accounting framework called System of Environmental Economic Accounting for Water (SEEAW). SEEAW describes hydrological and economic information through a set of standard tables and has also some supplementary tables to cover social aspects (UN, 2007). The SEEAW accounting components have precipitation, soil water, and evapotranspiration. This tool presents water from precipitation and the total amount of ET, excluding rainfall partitioning by different land use class. It does not show the beneficial of non-beneficial of depletion in term of ET.

The International Water Management Institute (IWMI) established a water accounting too. It demonstrated the water depletion instead of withdrawals. The water depletion is neglected recycling water and included evapotranspiration. The output per unit is provided in a means to simulation (Molden, 1997; Molden and Sakthivadivel, 1999). Water depletion are separated into two different types, beneficial and non-beneficial. The IWMI WA tool was designed for irrigation structures within a basin. However, it was later used for basin analysis. Some of the components of the IWMI WA are too generic for basin level studies. As the result, water depletion at irrigation service scale represents only crop evapotranspiration (Karimi et al., 2013).

The Australian organisation accounting is originally designed on SEEA-Water with runoff. Comparison of rainfall and ET, stream flows and rivers illustrate with a small fraction of the total water movement (Sivapalan et al., 2003). This tool accounting is to be withdraw water rather than water consumption. It is neglected the water being sink in water cycle. The Australian method studies irrigated agriculture, industrial and domestics water use. It presents the total water resources, economic, social, and benefit from the environment.

A common water accounting framework has so far been missing from the emerging debate on global water governance. The standard flow accounting method is heavily dependent on gauge data, thus while the development of water accounts is being prioritized in many parts of the world, it has been mostly limited to the wellgauged basins of Europe, Australia, the USA and Canada (Karimi, 2014; Molden and Sakthivadivel, 1999). However, the standard flow accounting method is heavily dependent on data. Application to relatively ungauged basins, such as the Niger, is therefore problematic at best. Additionally, most methods exclude natural landscapes, ET and rain-fed agriculture, which are important variables in the most basins (Karimi, 2014; Mainuddin et al., 2010), including the Tonle Sap Lake.

Water accounting is presented in Figure 1. It involves classifying water balance components into water-use categories that reflect the consequences of human interventions in the hydrologic cycle. Water accounting integrates water balance information with uses of water. Inflows into the domain are classified into various use categories as defined below.

Gross inflow is the total amount of water flowing into the water balance domain from precipitation, and surface and subsurface sources.

Net inflow is the gross inflow plus any changes in storage. If water is removed from storage over the time period of interest, net inflow is greater than gross inflow; if water is added to storage, net inflow is less than gross inflow. Net inflow is either
depleted or flows out of the water balance domain. Sustainability may be in question when net inflow differs from gross inflow over a long period of time.

Water depletion is a use or removal of water from a water basin that renders it unavailable or unsuitable for further use. Water depletion is a key concept for water accounting, as it is often the productivity and the derived benefits per unit of water depleted that are of primary interest. It is extremely important to distinguish water depletion from water diverted to a service or use, because not all water diverted to a use is necessarily depleted (Keller and Keller, 1995; Molden, 1997).

Beneficial depletion occurs when water is depleted in providing an input to produce a good such as an agricultural output, or providing a need such as drinking or bathing water, or in any other manner deemed beneficial such as supplying water for environmental uses (Molden and Sakthivadivel, 1999).

Committed water is that part of outflow that is allocated to other uses. For example, downstream water rights or needs may require that a certain amount of outflow be realized from an irrigated area. Or water may be allocated to environmental uses such as minimum stream flows, or outflows to sea to maintain fisheries.

Uncommitted outflow is water that is neither depleted nor committed, is available for a use within a basin or for export to other basins, but flows out due to lack of storage or operational measures.

Available water is the net inflow less the amount of water set aside for committed uses and less non-utilizable uncommitted outflow. It represents the amount of water available for use at the basin, service or use levels.

Non-depletive uses of water are uses where benefits are derived from an intended use without depleting water.

Depleted fraction ( $D F$ ) is that part of the inflow that is depleted by intended process uses. Defined in terms of gross inflow, depleted fraction is:

$$
\begin{equation*}
\text { DFnet }=\frac{\text { Depletion }}{\text { Grow inflow }} \tag{Eq. 1}
\end{equation*}
$$

Beneficial utilization (BU) indicates the percentage of water beneficially depleted. In terms of available water, it is:

$$
\begin{equation*}
\text { BUavailable }=\frac{\text { Beneficially depleted }}{\text { Available water }} \tag{Eq. 2}
\end{equation*}
$$

Productivity of water (PW), expressed in terms of available water, is:

Figure 1 Water accounting framework

Source: (Molden et al., 2003)

## 2. Water Accounting Plus

Water Accounting Plus (WA+) is a new framework that uses the IWMI WA principles of tracking water depletions rather than withdrawals. WA+ adopts the same definition for water depletion as the IWMI WA. It is often associated with withdrawals (Karimi et al., 2013). This new framework was considered on this study.

Water accounting involved classifying water balance components into water-use categories that reflected the consequences of human interventions in the hydrologic cycle. Water accounting integrates water balance information with uses of water as visualized conceptually (Molden and Sakthivadivel, 1999).

Inflows into the domain are classified into various use categories as defined below: There are four sheets for accounting, namely: (1) Resources base sheet, (2) Evapotranspiration sheet, (3) Productivity sheet and (4) Withdrawal sheet. In this study, we conducted for the first (1) and second (2) sheets.

### 2.1 Resource based sheet

The WA+ Resource based sheet is presented in Figure 2. It provides information on water volumes. Inflows are shown on the left of the resource base sheet diagram, the middle part provides information on how and through what processes the water is depleted within a domain, and information on exploitable water and reports on outflows are summarized on the right (Karimi et al., 2013).

Precipitation plus any surface or groundwater that flows to the domain from outside its boundaries is Gross inflow. Net inflow includes water storage changes over the period of accounting. The fresh water storage changes is surface water. The net inflow is partitioned into landscape ET and exploitable water present in streams, soils and aquifers. The landscape ET is a consequence of a certain rainfall distribution across a composite terrain with mixed land use, geological formations, soil types, slopes, elevations and natural drainage to streams. The net inflow minus landscape ET
can be referred to as exploitable water. It represents the portion of the net inflow that is not evaporated and is available for downstream use and withdrawals. The landscape ET is further divided into the four land use categories "conserved land use (CLU)", "utilized land use (ULU)", "modified land use (MLU)", and "managed water use (MWU)".

Not all of the exploitable water is available for use as part of it has to be reserved to meet downstream water right requirements (committed outflow, navigational flow and environmental flow). Guidelines for environmental flow are provided by for instance (Smakhtin, 2004). This water is called reserved outflow and is equal to the maximum of committed outflows, navigational flow and environmental flow. Exploitable water less reserved outflows is available water. It is the available water that can be allocated to various water use sectors. Part of the available water is depleted. This depleted water is called utilised flow and mainly takes place through incremental ET. The available water less the utilised water is utilisable water representing the amount of additional water that could be utilised. It represents the water that is not depleted, nor reserved, and is, thus, available for use within the basin or for export and intra basin water transfers. Depleted water is total ET. Outflows refer to the amount of water that physically leaves the basin through surface water system.

The resource based sheet in WA+ has a set of minimum performance indicators that are presented as fractions. These indicators are to help basin planners to understand the key information on water management in a basin, or any domain that water accounts are provided for. Time series of these indicators reveal trends. The impact of water policy interventions on water scarcity and benefits from water can be quantified. Exploitable water fraction is that part of the net inflow that is not lost to the landscape ET processes. The fraction relates to total run-off generated in a river basin and also exploited water from fresh water storage.

$$
\begin{equation*}
\text { Exploitable water fraction }=\frac{\text { Exploitable water }}{\text { Net inflow }} \tag{Eq. 4}
\end{equation*}
$$

Storage change fraction defines the degree of dependency on fresh storage change ( $\Delta \mathrm{Sfw}$ ). The fresh water resources are surface water storage, groundwater storage and total water storage. The negative values indicate storage depletion while positive values indicate that in the accounting period water storage has been increased in the domain.

$$
\begin{equation*}
\text { Storage change fraction }=\frac{\Delta \text { sfw }}{\text { Exploitable water }} \tag{Eq. 5}
\end{equation*}
$$

Available water fraction relates available water to exploitable water. It describes the portion of exploitable water that is actually available for withdrawals within a basin.

$$
\begin{equation*}
\text { Available water fraction }=\frac{\text { available water }}{\text { Exploitable water }} \tag{Eq. 6}
\end{equation*}
$$

Basin closure fraction describes to what extent available water is already depleted in a basin or domain. A closed basin is one where all available water is depleted. According to this definition a closed basin can still have substantial discharge in case all outflow is reserved.

$$
\begin{equation*}
\text { Basin closure fraction }=\frac{\text { Utilised flow }}{\text { Available water }} \tag{Eq. 7}
\end{equation*}
$$

Reserved outflows fraction relates the reserved outflows to outflow via streams and aquifers. It indicates whether the committed outflows are being met. The reserved outflows are intended to surface.

$$
\begin{equation*}
\text { Reserved outflow fraction }=\frac{\text { Reverved outflow }}{\text { Qout,surface water }} \tag{Eq. 8}
\end{equation*}
$$

Figure 2 Resource based sheet of the Tonle Sap Lake

### 2.2 Evapotranspiration sheet

The WA+ Evapotranspiration sheet (Figure 3) shows the processing of ET manageable or non-manageable that requires a value to specify beneficial and non-beneficial ET occurs through certain physical processes: evaporation (from soil, water), and interception evaporation from wet leaves and canopies (Rutter et al., 1971) and wet surfaces (e.g., buildings, roads). However, in some cases, interception evaporation is important for temperature regulation of plants and, hence, is beneficial. Transpiration (T) is the transfer of water by the plant to the atmosphere through stomata in the leaves. Water vapour transfer via transpiration and $\mathrm{CO}_{2}$ inhalation are biophysically linked (Monteith, 1988). While T is generally considered as beneficial, it can be considered non-beneficial in some cases such as weed infestations in cropland or in degraded landscapes, or when there are non-desirable plants. E is usually considered as non-beneficial as the vast majority of E originates from wet
soils (Choudhury and DiGirolamo, 1998). However, E from natural surface water is often beneficial.

Performance indicators for the WA+ evapotranspiration sheet provide key information on the magnitude of beneficial ET in a basin. Water use by key water users in a basin is expressed in term of fractions. Transpiration fraction is the part of ET that is transpired by plants and its reflects an impact on bio-physical process in water scare basin.

$$
\begin{equation*}
\text { Tfraction }=\frac{T}{E T} \tag{Eq. 9}
\end{equation*}
$$

Beneficial ET fraction relates E and T to the total ET in a basin.

$$
\begin{equation*}
\text { Beneficial fraction }=\frac{\text { Ebeneficial }+ \text { Tbeneficial }}{E T} \tag{Eq. 10}
\end{equation*}
$$

## 3. Previous Studied on Water Accounting and WA+

The IWMI WA has been applied to assess productivity of water use in several basins across the globe at various scales. Example of applications include Egypt's Nile (Molden et al., 1998). China's Yellow River basin, India's Krishna basin, Nepal's Indrawati basin, Indonesia's Singkarak-Ombilin River basin and Zhang IIe Irrigation District in China and the Karkheh River basin (Karimi et al., 2012b).

Molden and Sakthivadivel (1999) applied Water Accounting to different levels of analysis ranging from a micro level such as a household, to a macro level such as a complete water basin. Indicators are defined to give information on the productivity of the water resource. Examples from Egypt's Nile River and a cascade of tanks in Sri Lanka are presented to demonstrate the methodology.

Peter et al. (2010) applied WA+ on the Okavango River Basin which remained one of the watersheds least affected by human impacts on the African continent based on remote sensing and will therefore be easily applicable worldwide without the need of extensive field monitoring and data collection. Water Accounting, lack of data, has overcome in the proposed WA+ by relying heavily on satellite data.

Droogers et al. (2010) was applied WA+ in the Okavango River Basin using remote sensing data that collected from satellite images. Shilpakar et al. (2011) used remote sensing-based approach for water accounting in the East Rapti River Basin, Nepal. This study successfully demonstrated that the key inputs required for evaluating and monitoring the overall water resources conditions in a mountainous river basin can be computed from satellite data with a minimal support from ground information.

Karimi et al. (2012a) had presented Water Accounting for Indus Basin. Total area is $1,160,000 \mathrm{~km}^{2}$ which is shared by Pakistan, India, China, and Afghanistan, each respectively occupying $53,33,8$, and $6 \%$ of the basin area. With a population of
about 250 million, the basin is among three major highly populated river basins in South Asia alongside Ganges and Brahmaputra Basins.

## MATERIALS AND METHODS

## 1. Study Area

The Tonle Sap Lake is the largest permanent freshwater lake, locating in Cambodia at the Lower Mekong River basin (Campbell et al., 2009). During the dry season, the lake is about 120 km long and 35 km wide with an area of about $2,500 \mathrm{~km}^{2}$. During the flood period, the lake expands to 250 km long and 100 km wide with an area of about $17,500 \mathrm{~km}^{2}$, and the depth reaches $8-10 \mathrm{~m}$. The Tonle Sap basin is $85,796 \mathrm{~km}^{2}$ in total, extends over $44 \%$ of Cambodia's total area. It is shared by Cambodia $95 \%$ and Thailand 5\% of the total basin area (Campbell et al., 2006; Junk et al., 2006). There are five provinces bordering Tonle Sap Lake namely: Siem Reap, Battambang, Pusat, Kampong Cham, and Kampong Thom. The Tonle Sap Basin consists of 11 river basins namely (ST1) Stung Baribor, (ST2) Stung Chikreng, (ST3) Stung Chinit, (ST4) Stung Dauntri, (ST5) Stung Mongkol Borei, (ST6) Stung Pursat, (ST7) Stung Sangker, (ST8) Stung Sen, (ST9) Stung Siem Reap, (ST10) Stung Sreng and (ST11) Stung Staung. The Tonle Sap Lake location is presented in Figure 4. Area of each basin is summarized in Table 1.

Table 1 Subtotal area of each basins

| Basin code | Basin name | Area $\left(\mathbf{k m}^{2}\right)$ |
| :--- | :--- | ---: |
| ST1 | Boribor | 7,152 |
| ST2 | Chikreng | 2,713 |
| ST3 | Chinit | 8,235 |
| ST4 | Dauntri | 3,695 |
| ST5 | Mongkolborey | 15,020 |
| ST6 | Pursat | 5,963 |
| ST7 | Sangke | 6,051 |
| ST8 | Sen | 16,340 |
| ST9 | Sieamreap | 3,618 |
| ST10 | Sreng | 9,930 |
| ST11 | Staung | 4,356 |
|  | Tonle Sap Lake | 2,723 |
| Total |  | $\mathbf{8 5 , 7 9 6}$ |

The Tonle Sap Lake basin is located in the tropical region with wet and dry season. Average daily temperatures vary between about $20^{\circ} \mathrm{C}$ and $36^{\circ} \mathrm{C}$ (Figure 5) with lowest temperatures in January and highest in April (Campbell et al., 2006).

The Tonle Sap River, which flows from the south-eastern end of Tonle Sap Lake, joins the Mekong River at the Chaktomuk confluence, in the vicinity of Phnom Penh. After the confluence, the river immediately splits into the smaller Bassac River and the larger Mekong River. In the wet season, from May to September, flooding and the associated water level increase in the Mekong River causes the Tonle Sap River to change flow direction and flow towards the northwest (upstream) into Tonle Sap Lake (Kummu et al., 2014).

## 2. Water Accounting Plus Method

Water Accounting Plus (WA+) in Tonle Sap Lake is a method to access with satellite images, which help to understand and interpret satellite images information. Moreover, evapotranspiration, rainfall, and land-use has been taken into account in this study.

Depletion water accounting frameworks, such as WA+, have been trialled in recent years to focus on the consumptive use of water including water consumption for natural processes (green water consumption) as well as human uses (blue water consumption) (Falkenmark and Rockström, 2006; Karimi, 2014). Water accounting methods is following as:

$$
\begin{equation*}
Q=P-E T \pm \Delta S \tag{Eq. 11}
\end{equation*}
$$

Where $Q$ is discharge ( $\mathrm{mm} / \mathrm{yr}$ ), P is precipitation ( $\mathrm{mm} / \mathrm{yr}$ ), ET is the sum of actual evaporation and transpiration ( $\mathrm{mm} / \mathrm{yr}$ ) and $\Delta S$ is changes in storage.

### 2.1 Land-use classes in water accounting plus

Land use classification is most basic work to research land use, it direct affected the research and practice of land use (Mingzhou, 1997). Land use/land-cover is one of the most important factors affecting runoff and evapotranspiration in the watershed (Setegn et al., 2010).

Table 2 Definition of landuse classes on WA+

| Conserved land use (CLU) | Utilized land use (ULU) | Modified land use (MLU) | Managed water use (MWU) |
| :---: | :---: | :---: | :---: |
| Area no changes in land water are possible or advisable. | Human influences is limited, vegetation is not managed on a regular basis. | Area where vegetation/ soils are managed. | All sectors that withdraw water from surface water and or groundwater. |
| Examples: wetlands, tropical rainforests, mountainous vegetation, national parks. | Examples: forests, natural pastures, savannas, deserts. | Examples: rainfed agriculture, built up and urban area. | Examples: <br> irrigated agriculture urban water supply and industrial extraction. |

Table 3 General landuse classes of WA+

| Conserved land use | Utilized land use | Modified land use | Managed water use |
| :---: | :---: | :---: | :---: |
| Reserves or national park | Closed natural forest | Plantation trees | Irrigated pastures |
| Areas set aside for conservation | Tropical rain forest | Rainfed pastures | Irrigated crops |
| Glaciers | Open natural forest | Rainfed crop | Reservoir |
| Coastal protection | Woody savanna | Rainfed fruit | Greenhouses |
|  | Open savanna | Rainfed biofuels | Aquaculture |
|  | Natural pastures | Parks | Residential area |
|  | Deserts | Fallow Land | Industrial area |
|  | Mountains | Urban | Parks |
|  | Rocks |  | Managed wetland |
|  | Flood plains |  | Inundation areas |
|  | Bare land |  | Mining |
|  | Waste land |  | Evaporation ponds |
|  | Wetland |  | Waste water treatment |
|  | swamps |  | Power plants |

## 3. Water Balance Analysis on the Tonle Sap Lake by WEAP Model

The Water Evaluation and Planning (WEAP) model was developed by the Stockholm Environment Institute (SEI). It operates at a monthly step on the basic principle of water balance accounting. The user represents the system in terms of its various sources of supply (e.g. rivers, groundwater, and reservoirs), withdrawals, water demands, and ecosystem requirements (Lévite et al., 2003). The water balance schematic of all sub-basins is presented in Figure 10.

Model elements can fall into two main categories: nodes, where water is demanded or made available for supply, and links, which transfer water between the nodes. The water management model is driven by user-defined demand priorities, supply preferences and environmental requirements for the various nodes. The water allocation problem is solved using linear programming on a daily or monthly basis (Psomas et al., 2016).

Maliehe and Mulungu (2017) presented as WEAP operates on a monthly time step water balance accounting: total inflows equal total outflows, net of any change in storage (in reservoirs and aquifers). A linear programming is used to maximize the satisfaction of demand site and user-specified in stream flow requirements, subject to demand priorities, supply preferences, mass balance and other constraints.

## 4. Data Processing

In this study, rainfall and evapotranspiration datasets have been extracted from the satellite-derived data by the Google Earth Engine platform. It is a part of remote sensing concept.

### 4.1 Remote sensing

Remote Sensing is unique in that it can be used to collect data, unlike other techniques, such as thematic cartography, geographic information systems, or
statistics that must rely on data that are already available. Remote sensing is defined, for purposes, as the measurement of object properties on the earth's surface using data acquired from aircraft and satellites (Schowengerdt, 2006). WA+ is based on remote sensing and will therefore be easily applicable worldwide without the need of extensive field monitoring and data collection and in ungauged and poorly gauged basins (Droogers et al., 2010).

### 4.2 Google earth engine

Recently, the Google Earth Engine (GEE) leverages cloud computing services to provide analysis capabilities on over 40 years of Landsat data (Dong et al., 2016). Google Earth Engine (GEE) platform facilitates a fast analysis by using Google's cloud-computing infrastructure (https://earthengine.google.org/). It is a cloud-based platform that makes it easy to access high-performance computing resources for processing very large geospatial datasets (Gorelick et al., 2017). As a remote sensing platform, its ability to analyze global data rapidly lends itself to being an useful tool on data visualization (Patel et al., 2015). Additionally, dataset is processing of geospatial on the online complex spatial analyses using the Javascript Application Programming Interface (API). This API can be developed a code in order to request datasets of publicly available remotely sensed imagery and other data.

The pre-processed daily data of Tropical Rainfall Measuring Mission, or TRMM 3B42V7, biomass and 8-day Potential evapotranspiration (PET) datasets are available datasets through GEE. It was used to assess data sources across the study area by GEE script from 2000 to 2014. All datasets have been summarized into yearly and monthly via JavaScript, excepted biomass in yearly. The example of code is presented in Figure 6. For more detail coding can assess via this link on the GEE (https://code.earthengine.google.com/ec0763b56fea94628615c48ee2acdac8). For further information is presented in Appendix B.

Figure 7 Gauge stations and water level stations
5.2 Rainfall and evapotranspiration

Figure 8 Rainfall stations of the Tonle Sap Lake basin

Precipitation is a critical variable in the global hydrologic cycle, and it influences our daily lives (drought, floods, agricultural, irrigation, outdoor activities, etc.). Precipitation is the primary input for WA+. A new technique is presented in which half-hourly global precipitation. It estimates derived-data from passive microwave satellite scans. The frequency passive microwave (PMW-derived precipitation estimates that are presently used in the Climate Prediction Center morphing method (CMORPH) are generated from observations obtained from the National Oceanic and Atmospheric Administration (NOAA) polar-orbiting operational meteorological satellites, the U.S. Defense Meteorological Satellite Program (DMSP) satellites, and from the Tropical Rainfall Measuring Mission satellite (Joyce et al., 2004).

Since its launch in 1997, the Tropical Rainfall Measuring Mission (TRMM) has provided precipitation estimates that have been widely used in tropical cyclone (TC) rainfall studies (Lonfat et al., 2004). The TRMM 3B42 (V7) three-hourly, $0.25^{\circ} \times 0.25^{\circ}$ product is used in this study. This product depends on input from two different types of sensors, namely microwave and IR. The three-hourly estimates are produced in four stages: (1) the microwave estimates are combined, (2) IR estimates are created with microwave calibration, (3) the microwave and IR are combined such that the microwave estimates are taken "as is" with the IR estimates used to fill the gaps, and (4) finally, gridded monthly rain gauge analyses are used to rescale the TRMM satellite precipitation estimates to remove bias where possible to create the final TRMM 3B42 product (Huffman et al., 2007). It is available from 1998 to present at https://pmm.nasa.gov/data-access/downloads/trmm.

CHIRPS stands for Climate Hazards Group IR Precipitation Station and is a third generation precipitation procedure which is based on various interpolation schemes to create spatially continuous grids from raw point data. CHIRPS incorporates $0.05^{\circ}$ resolution satellite imagery (Funk et al., 2014). CHIRPS was created in collaboration with scientists at the U.S. Geological Survey (USGS) Earth Resources Observation and Science (EROS) Center in order to deliver reliable, up to date, and more complete datasets for a number of early warning objectives (such as trend analysis and seasonal drought monitoring) (Funk et al., 2015). The available data is from 1981 to near present.

PERSIANN-CDR stands for Precipitation Estimation from Remotely Sensed Information Using Artificial Neural Networks-Climate Data Record. PERSIANN primarily uses infrared brightness temperature data from geostationary satellites to estimate rainfall rate, updating its parameters using PMW observations from low-orbital satellites. The PERSIANN half-hourly $0.25^{\circ}$ rain-rate product is available for March 2000 to the present (Hsu et al., 1997). The version 7 TMPA data product (Huffman et al., 2007) has 3-hourly and $0.25^{\circ}$ temporal and spatial resolution, respectively, starting from January 1998.

Evapotranspiration is one of the most important components of the hydrological cycle. Combined with rainfall and runoff, it controls the availability and distribution of water at the Earth's surface, and for this reason, is of significance to a number of water-related research and application areas. Quantifying the spatial variability in hydrological and land surface variables is important to water resource management, particularly in agricultural regions (McCabe and Wood, 2006).

The MOD16A2 V105 product provides information about 8-day global terrestrial potential evapotranspiration at 1 km pixel resolution. Evapotranspiration (ET) is the sum of evaporation and plant transpiration from the Earth's surface to the atmosphere. With long-term ET data, the effects of changes in climate, land use, and ecosystems disturbances can be quantified data which is based on the PenmanMonteith method and calculates both canopy conductance and ET (Running et al., 2017).

### 5.3 Landuse type of the Tonle Sap Lake basin

In this study, landuse type of the lake basin has been obtained from the Mekong River Committee on 2003 (Figure 9). The main landuse types in this study area are agricultural lands or rice fields, wetland, forest, open water or lake. The area of each landuse type has summarized in Table 5.

Figure 9 Landuse type of the Tonle Sap Lake basin

Table 5 Landuse classes of the Tonle Sap Lake basin

| Land-use classes | WA+ classes | $\begin{aligned} & \hline \text { Area } \\ & \left(\mathbf{k m}^{2}\right) \end{aligned}$ | \% |
| :---: | :---: | :---: | :---: |
| Woodland and Scattered trees | CLU | 5,472.09 | 6.38 |
| Forest | CLU | 2,022.28 | 2.36 |

| Total watershed area |  | 85,796.00 |  |

### 5.4 Reclassification of landuse classes of the Tonle Sap Lake basin

Figure 10 Landuse classification on the Tonle Sap Lake basin

Based on the landuse classes of Water Accounting Plus categories, there are four type of landuse type (Figure 10). Based on the Table 5, the highest one is Utilized Land Use around $51899 \mathrm{~km}^{2}$, following by Modified Land Use ( $22859 \mathrm{~km}^{2}$ ), Conserved Land Use ( $7585 \mathrm{~km}^{2}$ ) and Managed Water Use ( $3451 \mathrm{~km}^{2}$ ).

## 6. Methodology

### 6.1 Overall framework

The general framework is presented in Figure 11. The Google Earth Engine (GEE) was the main platform to retrieve satellite-derived data such as rainfall and ET during these study periods from 2000 to 2014. To reach these goals, a JavaScript has been coded on the GEE server platform in order to evaluate the datasets. Datasets availability depend on the temporal of satellite images which is available on the free open access.

The Water Evaluation and Planning (WEAP) model was the first priority to be used satellite-derived data (rainfall and ET). Both datasets were input into model to complete water balance components analysis of the Tonle Sap Lake Basin. In this model, schematic of the sub-basins were drawn based on study area shapefile as a background. Moreover, rainfall and potential evapotranspiration of each sub-basins were also used as input data. Storage of the lake and water level has been input. Water balance approach, in this case, landuse of the Tonle Sap Lake Basin has been reclassified to four different categories of water accounting plus by the Geographic Information System (GIS). Another thing to note is streamflow was calibrated using the Parameter Estimation Tool (PEST). Calibration depended on the data availability from the streamflow gauge stations during this study period. After this process, water balance components of the lake were conducted in term of water volume such as surface inflow from the Mekong River, rainfall, exchanged flow between the Tonle Sap Lake and the Mekong River, actual evapotranspiration (ETa) and others.

The last part of this objective, Water Accounting Plus (WA+) sheets (Resource based and Evapotranspiration sheets) have been considered in term of WA+ framework. Datasets were prepared using data from the water balance analysis. Hence, WA+ sheets has been conducted in term of four different land-use categories such as Conserved Land Use, Modified Land Use, Utilized Land Use and Managed

Water Use. All data were presented to gross inflow, storage change, depleted water and outflow of the lake.

Figure 11 General framework
6.2 Water balance analysis of the Tonle Sap Lake

The water balance analysis relies on the Law of Conservation of Mass, which requires that, for a specified domain over a specified period of time, water inflows are equal to water outflows, plus or minus any change of storage (Batchelor et al., 2017). The water balancing of Tonle Sap Lake was based on the equation:

$$
\begin{equation*}
S_{i}=S_{i-1}+I_{i}+I_{M K, i}-O_{M K . i}-N E T_{i} \tag{Eq. 12}
\end{equation*}
$$

where $S_{i-1}$ and $S_{i}$ are the storage of the Tonle Sap Lake at the beginning and the end of each time step, $I_{i}$ is the inflow from the Tonle Sap watershed, $I_{m K, i}$ is the
inverse flow in Tonle Sap River from the Mekong River, $O_{i}$ is the outflow to the Mekong River, and $N E T_{i}$ is the net evaporation which equals to the difference between the potential evapotranspiration and rainfall over the lake surface ( $P E T_{i}-P_{i}$ ). The lake surface-area and volume were estimated using the relationships proposed by Kummu et al. (2014):

$$
\begin{gathered}
V=0.7307 \times W L^{2}-0.3554 \times W L+0.9127 \\
A=5.5701 \times \mathrm{WL}^{3}+1.374 \times W L^{2}+470.29 \times W L+1680.2
\end{gathered}
$$

Eq. 13
Eq. 14
where, $A$ is surface area of the lake $\left(\mathrm{km}^{2}\right), V$ is volume of the lake $\left(\mathrm{km}^{3}\right)$ and $W L_{K L}$ represents the water level of Tonle Sape Lake measured at Kampong Loung (KL) station in meter above mean sea level (MSL). Water level of each stations is presented in Appendix G.

Figure 12 Tonle Sap Lake characteristic

The balancing of inflows and outflows was calculated by the Water Evaluation and Planning System or WEAP model. The WEAP model is developed by
the Stockholm Environment Institute (SEI, 2016). The model fundamentally operates on monthly time-step. The watershed of Tonle Sap Lake was divided into 11 subbasins and represented in the model as shown in Figure 13.

Figure 13 Schematic of the Tonle Sap Lake system represented in WEAP model
6.3 Estimation of exchanged flow between the Mekong and Tonle Sap Lake

The Mekong River and the Tonle Sap Lake have a great significance of exchanged flow. The water level of the river and the lake are related to seasonal pattern. The Tonle Sap River functions naturally as tributary of the Mekong River. Outflow from the Tonle Sap Lake takes place between mid-September and early May. Between early May and mid-September, the inversed flow in the Tonle Sap River occurs when the water levels in the Mekong River are higher than those in the lake. The estimations of exchanged flow between Tonle Sap Lake and Mekong river were followed the relationships proposed by Kummu et al. (2014):

$$
\begin{equation*}
\mathrm{F}_{\text {in }}=\mathrm{F}_{\text {out }}=\mathrm{WL}_{\mathrm{PK}}^{1.2} \times\left(\left|\mathrm{WL}_{\mathrm{PP}}-\mathrm{WL}_{\mathrm{KL}}\right|\right)^{0.5} \tag{Eq. 15}
\end{equation*}
$$

$$
\begin{align*}
& \mathrm{Q}_{\text {in }}=-15.0467 \times \mathrm{F}_{\text {in }}{ }^{2}+859.839 \times F_{\text {in }}-782.264  \tag{Eq. 16}\\
& Q_{\text {out }}=8.784 \times F_{\text {out }}{ }^{2}+434.465 \times F_{\text {out }}+167.151 \tag{Eq. 17}
\end{align*}
$$

where, $W L$ is the water level (MSL), $W L_{P K}$ at Prek Kdam, $W L_{P P}$ at Phnom Penh Port, $W L_{k L}$ at Kampong Loung, $Q_{\text {in }}$ is inversed flow into the Lake, $Q_{\text {out }}$ is outflow from the Lake.

### 6.4 Estimation of streamflow of Tonle Sap tributaries

The WEAP model implements several rainfall-runoff methods from simple coefficient, soil moisture, to complex plant-growth simulation. In this study, the MABIA method, which based on the FAO-56 dual crop-coefficient approach (FAO, 1998) was selected. Although the time-step for MABIA is daily, the time-step for the rest of your WEAP analysis does not need to be daily. For each WEAP time-step (e.g., monthly), MABIA would run for every day in that time-step and aggregate its results to that time-step. Groundwater-surface water interactions were also taken into an account. Groundwater flow to stream was estimated as the percentage of monthly streamflow, first derived by a built-in PEST calibration module in WEAP.

## RESULTS AND DISCUSSION

## 1. Comparison of Satellite Rainfall Data to Observation

Based on the Table 6, Persian, Chirp and TRMM have been compared to the observation. The result showed that TRMM is high correlation ( $\mathrm{r}=0.98$ ) compared to observation during this study period on 2010. Chirp and Persian satellite-derived data were also provided a high correlation. Both $r$ datasets were 0.96 . Hence, TRMM was selected to simulate during this study periods from 2000 to 2014. For further detail on rainfall data during this study periods is presented in Appendix C.

Table 6 Statistical indicator of satellite rainfall of the Tonle Sap Lake basin

| Indicator | Persian | Chirp | TRMM |
| :---: | ---: | ---: | ---: |
| r | 0.96 | 0.96 | 0.98 |
| Mean | -9.88 | -8.58 | 1.38 |
| Error |  |  |  |

## 2. Rainfall and Actual ET

The average of annual rainfall varied from $1,338 \mathrm{~mm}$ in dry year 2010 to $1,974 \mathrm{~mm}$ in wet year in 2011 during these study periods as shown in Figure 14. Mean annual rainfall was about $1,700 \mathrm{~mm}$. The heavy rainfall is seasonal, mainly occurring between April and November, with a peak of 332 mm in September (Appendix C).

The mean actual ET (ETa) was 1463 mm . It varied from 1276 mm to 1709 mm . Monthly data presented in Figure 15. The average monthly actual evapotranspiration varies between 14 mm and 188 mm (Appendix D). January was a high ET in dry season. However, this occurred might be as the amount of water containing in high during the end of wet season. So, it affected to the beginning of dry season which was high ETa in this month. Other month to note is February was released less water in term of ETa. It might be contained less water in soil moisture during this month.

Figure 14 Yearly rainfall and actual ET of the lake

Figure 15 Monthly rainfall and actual ET of the lake

## 3. The Estimation of Streamflow of the Tonle Sap Lake Basin

Figure 16 to 26 showed the stream flow from sub basins of the Tonle Sap Lake. In Table 7, mean monthly rainfall in sub-basins are presented. In Table 8, mean monthly stream flow in sub-basins are also showed. ST7 received the highest rainfall during this study periods 2049 mm per year. The lowest rainfall is on the basin ST9 1510 mm per year.

Table 8 Average rainfall data of each sub-basins

| Month | ST1 | ST2 | ST3 | ST4 | ST5 | ST6 | ST7 | ST8 | ST9 | ST10 | ST11 |

The high stream of each basin occurs during the wet period from May to October. ST8 received the highest stream flow compared to all sub-basins. It showed that streamflow is varied between $0.77 \mathrm{~m}^{3} \mathrm{~s}^{-1}$ during the dry period and $50 \mathrm{~m}^{3} \mathrm{~s}^{-1}$ during the raining season.

The estimation of streamflow of each sub-basin was used the amount of rainfall. It was translated to the streamflow of each sub basin. It showed clearly that during the raining season the streamflow is also high. Otherwise, streamflow is low during the dry season.

### 3.1 Streamflow calibration on ST8

In this study, sub-basin ST8 (Figure 27) has been calibrated using PEST tool which it is based on the streamflow gauge. It also had streamflow gauge stations from 2000 to 2011. ST8 is a biggest basin among the other sub-basins. So, it is high influence to the Tonle Sap Lake. The result showed that the model performed less well during the raining season. The simulation is over estimated during the wet period with $R^{2}=0.6$ (Figure 28).

Figure 27 Observed vs. simulated streamflow of ST8

Figure 28 Scatter plot between observed and simulated streamflow of ST8

Table 10 Value of parameters calibration

| Parameter | CLU | ULU | MLU | MWU |
| :--- | ---: | ---: | ---: | ---: |
| Surface Layer Thickness (m) | 0.3 | 0.3 | 0.3 | 0.3 |
| Total Soil Thickness (m) | 1.5 | 1.5 | 1.5 | 1.5 |
| Soil Water Capacity (\%) | 16 | 16 | 14 | 16 |
| Max Percolation (mm/day) | 1.5 | 1.5 | 0.7 | 1.5 |

Some parameters had high influence to the streamflow are presented in Table 10. The parameters of the basin has affected to the streamflow calibration was surface layer thickness around 0.3 m . Total soil thickness was around 1.5 m . Max percolation varied between 0.7 and 1.5 mm per day.

### 3.2 Observed and simulated volume

Over the fifteen-year simulated period from 2000 to 2014, the model indicated very well $\left(\mathrm{R}^{2}=0.94\right)$ with observed volume of the Lake compared to simulated volume. However, the model performed less well during the end of the dry and wet season, shown in Figure 29.

Figure 29 Observed vs. simulated lake volume

This problem should be occurred due to relationship between the water level of the Tonle Sap lake and the Mekong River. Bio direction changing of the Tonle Sap Lake, it might be affected to water level accuracy of the stations during the end of dry and wet periods. So, model provided not good simulation during these changing.

## 4. Water Balance Components of the Tonle Sap Lake

Based on the result in Figure 30 and Table 11, the water balance analysis showed that the mean annual inflow of water balance of the lake ranged from 46.19 $\mathrm{km}^{3}$ to $89.62 \mathrm{~km}^{3}$. The highest inflow occurred in 2011 during the worst flood season on the lower Mekong River. The estimated average inflow of the lake was $69.28 \mathrm{~km}^{3}$ during this study period over fifteen years. The mean yearly outflow was estimated $69.25 \mathrm{~km}^{3}$ over the study period. The estimated mean outflow varied from $49.21 \mathrm{~km}^{3}$
to $86.55 \mathrm{~km}^{3}$. The annual inflow of Mekong River to the Tonle Sap Lake was estimated from $32.43 \mathrm{~km}^{3}$ to $53.43 \mathrm{~km}^{3}$ during these study periods over fifteen years. The mean annual inflow was $43.14 \mathrm{~km}^{3}$. It showed that the Mekong River is the highest influence on the lake. The annual inflow from the watershed varied from 12 $\mathrm{km}^{3}$ to $36 \mathrm{~km}^{3}$.

On monthly time series, the Mekong River has an effect on the Tonle Sap Lake during the raining season from May to October were 0.4 to $15.6 \mathrm{~km}^{3}$ respectively. The high inflow from the Mekong River to the lake occurs during June and September, shown in Figure 31.

The storage changes of the Lake on the end of each year showed that it varied from $15.86 \mathrm{~km}^{3}$ for the dry year to $32.50 \mathrm{~km}^{3}$ for the wet year.

Table 11 Summarized water balance components of the Tonle Sap Lake

| year | Rainfall <br> of <br> watershed | Inflow <br> from <br> watershed | Inflow from <br> Mekong River | Total <br> inflow | Total <br> outflow | Storage <br> on the 31st <br> December |  |

(\%) of inflow from the Mekong River compared with total inflow

Figure 30 Yearly water balance components of the lake

Figure 31 Monthly water balance components of the lake

Water balance analysis showed that the Mekong River is the main part of the Tonle Sap Lake. It retained more than half percent of the total inflow. And the lake's
watershed was also important. It takes place more than thirty percent compared to total inflow.

## 5. Water Accounting Plus Sheets

The water accounting plus resource base and evapotranspiration sheets described below: resource based was divided into three main parts based on yearly, dry season and wet season. For the evapotranspiration sheet summarized into yearly during this study periods.

### 5.1 Resource based sheet

The components of resource based sheet is presented in Table 12. It was summarized into its frameworks. Annually, the water accounting plus resource base sheet is summarized in Figure 32. Surface inflow was $43.14 \mathrm{~km}^{3}$. The gross precipitation was $153.56 \mathrm{~km}^{3}$. Gross inflow was 196.70 and net inflow was equal to gross inflow. These are derived from rainfall of the Mekong River, catchment of the Tonle Sap Lake and the lakes itself. Additionally, the storage change was neglected on annually simulation. The net inflow was separated into four categories: Conserved Land Use $11.69 \mathrm{~km}^{3}$ for forests, Utilized Land Use $72.87 \mathrm{~km}^{3}$, Modified Land Use $36.72 \mathrm{~km}^{3}$ for agricultural lands and Managed Water Use $6.23 \mathrm{~km}^{3}$ for the water bodies in term of depletion "Landscape Evapotranspiration (ET) $127.70 \mathrm{~km}^{33}$ ". The majority of water depleted was $57 \%$ for ULU land use type. These are forests, plants, grasslands, bamboos forests, shrub lands, barren lands and wet lands. The water volume outflow was $96.24 \mathrm{~km}^{3}$ which flew into the downstream of the Tonle Sap Lake. It was assumed to be committed flow $13.84 \mathrm{~km}^{3}$ which is the amount of stored water in the lake and uncommitted flow $55.39 \mathrm{~km}^{3}$ which is available outflow into the downstream.

In the dry season accounting, the water accounting plus resource base sheet is presented in Figure 33. Surface inflow was $0.1 \mathrm{~km}^{3}$. The net inflow was $87.94 \mathrm{~km}^{3}$ (gross inflow $21 \mathrm{~km}^{3}$ plus storage change $66.73 \mathrm{~km}^{3}$ and surface inflow). The
depleted water was into four categories in term of ET: Conserved Land Use $4.01 \mathrm{~km}^{3}$, Utilized Land use $23.35 \mathrm{~km}^{3}$, Modified Land Use $12.65 \mathrm{~km}^{3}$ and Managed Water Use $2.75 \mathrm{~km}^{3}$. The water volume outflow was $42.98 \mathrm{~km}^{3}$ which flew into the downstream of the Tonle Sap Lake. It was to be committed flow $8.60 \mathrm{~km}^{3}$ and uncommitted flow $34.38 \mathrm{~km}^{3}$.

In the wet season accounting, the water accounting plus resource base sheet is demonstrated in Figure 34. Surface inflow was $43.14 \mathrm{~km}^{3}$. The net inflow was $116.95 \mathrm{~km}^{3}$ (gross inflow $153.56 \mathrm{~km}^{3}$ plus storage change $-66.99 \mathrm{~km}^{3}$ and surface inflow). The water depletion was $8.22,50.93,25.77$ and $3.75 \mathrm{~km}^{3}$ for Conserved Land Use, Utilized Land Use, Modified Land Use and Managed Water Use respectively. The water volume outflow was $28.29 \mathrm{~km}^{3}$ which flew into the downstream of the Tonle Sap Lake. The committed and uncommitted flow were $5.66 \mathrm{~km}^{3}$ and $22.63 \mathrm{~km}^{3}$.

Table 12 Resource based sheet components

| Components | Yearly | Nov-Apr | May-Oct |
| :---: | ---: | ---: | ---: |
| Rainfall (watershed) | 143.563 | 19.778 | 131.838 |
| Lake rainfall | 9.970 | 1.220 | 8.965 |
| Surface inflow | 43.144 | 0.009 | 43.135 |
| Storage change | 0.000 | 66.730 | -66.990 |
| Outflow | 69.248 | 42.980 | 28.286 |
| Uncommitted | 55.399 | 34.384 | 22.629 |
| Committed | 13.850 | 8.596 | 5.657 |

Figure 32 Annual resource based sheet components

Figure 33 Seasonal (May to October) resource based sheet components

Figure 34 Seasonal (Nov-Apr) resource based sheet components

During the annual simulation, the lake retained high inflow from rainfall around 78 percent compared to net inflow. Inflow from the Mekong River also showed high one around 22 percent. The highest water depletion was more than half percent and, outflow was only 35 percent. For the seasonal based sheet showed that the highest depleted water occurred during wet season around 76 percent. Only 24 percent was released to downstream. Moreover, storage change of the lake was also an important role to the lake. It affected to the volume water on seasonal.

### 5.2 Evapotranspiration sheet

The water depletion in term of ET each land use class are presented in Table 13. The WA+ Evapotranspiration sheet illustrated in Figure 35. This sheet divided the total of depleted water $127.52 \mathrm{~km}^{3}$ into CLU $11.69 \mathrm{~km}^{3}$ (9\%), ULU 72.88 $\mathrm{km}^{3}$ ( $57 \%$ ), MLU $36.72 \mathrm{~km}^{3}$ (29\%) and MWU $5.23 \mathrm{~km}^{3}$ (5\%). Evaporation and
transpiration were depleted $40.25 \mathrm{~km}^{3}$ ( $31.6 \%$ ) and $87.28 \mathrm{~km}^{3}$ ( $68.4 \%$ ) respectively. All from E is non-beneficial and T is beneficial. Indicators is presented in Table 14.

Table 13 Components of evapotranspiration sheet

| Time <br> scale | Land use <br> class | CLU | MLU | MWU | ULU | Total |
| :---: | :---: | ---: | ---: | ---: | ---: | ---: |

Figure 35 Annual evapotranspiration sheet components in $\mathrm{km}^{3}$

The evapotranspiration sheet provided the water depletion in term of different categories. The highest water depletion was in Utilized Land Use classes. It take place more than half However, this landuse type, most of water depletion
occurred from wetlands. Hence, no method has been described to conserve water. Modified Land Use also demonstrated a high one around 29 percent which happened to the agriculture land. To maintain this amount of water, It is to be attention on water use for agriculture by improving land productivity. These will be a help to decrease water consumption and increase production. The main sources for reducing water depletion is to reduce soil evaporation.

### 5.3 Indicators of WA+ sheets

The WA+ provided some indicators of each sheets (Table 14). In the Tonle Sap basin, the annual resource based sheet, exploitable water fraction was 0.35 which represented the portion of exploitable water compared to net inflow. It showed that a less water was flow out to downstream. The seasonal from May to October also demonstrated that the amount of water was less outflow (0.24). However, from November to April, it was 0.49. Around half of net inflow in the Tonle Sap Lake indicated as outflow.

For the evapotranspiration sheet, T fraction ratio was 0.68 , meaning the majority of water depletion from forests. All of these depleted water was beneficial. Moreover, this ration showed that the less water depleted in the Tonle Sap Lake basin was through soil and water.

Table 14 Indicators of WA+ sheets

| Time <br> step | Indicators | Resource Based <br> Sheet | Evapotranspiration <br> Sheet |  |
| :--- | :--- | :--- | :--- | :--- |
|  | Exploitable Water Fraction | 0.35 |  |  |
| Annual | Tfraction |  | 0.68 |  |
|  | Beneficial fraction |  | 0.24 | 0.68 |
| May-Oct | Exploitable Water Fraction |  |  |  |
| Nov-Apr | Exploitable Water Fraction | 0.49 |  |  |

# CONCLUSION AND RECOMMENDATION 

## Conclusion

In this study, the water balance in term of water accounting of the Tonle Sap and its sub-basins was considered as simulation using satellite derived data coupling the Google Earth Engine (GEE) from 2000 to 2014. It showed that satellite derived data can provide a good understanding on the water resource management. To sum up, the water accounting framework can provide the information on the water resource management of the Lake coupling the remote sensing concepts. It was achieved a good first step on earth observation data during the simulated periods on water balance analysis in term of the water accounting of the Tonle Sap Lake. Additionally, the focus of this study focused on the WA+ resource based sheet and evapotranspiration sheet. The components of the water balance discharge of the lake have the lake's catchment, inflow from the Mekong River into the Tonle Sap Lake via the Tonle Sap River and lake itself. The inflow from the catchment into the lake was estimated as the surface runoff from all sub-basins surrounding the lake. The analysis was conducted on annual from 2000 to 2014, dry season from November to April and wet season from May to October.

The results of the water balance analysis showed that the large amount of water from the Mekong River takes high place into the Tonle Sap Lake around 62 percent compared to total inflow into the lake, but the lake's catchment also plays as an important role 36 percent of annual flow, and 2 percent is retrieved from rainfall of the lake itself. Moreover, The Mekong River has high effected inflow into the lake during the raining season from June to September and less inflow during the beginning and the end of wet season.

For the water accounting plus, the result showed that the water outflow is highest during the dry season. The results suggest that the Tonle Sap Lake need to introduce bidirectional control structures in order to conserve water during the dry season. Control structures can maintain these amount of water to use for drought
season. However, this solution will be affected on flow regime of the lake, as well as ecosystem.

The depleted water in term of ET from ULU land use type is higher than others, following by MLU. These are agriculture, wetlands, barren lands or wilderness and shrub lands. Therefore, to improve the situation in water depletion, it can be reforestations on wetlands, barren lands or wilderness. Moreover, it is to be attention on water use for agriculture by improving land productivity. These will be a help to decrease water consumption and increased production. The main sources for reducing water depletion is reduce soil evaporation.

## Recommendation

In this study, the earth observation was provided the main input data sources for the model. However, these data require the ground observation for the calibration process. It could cause some uncertainty and errors on satellites data parameters.

#### Abstract

Precipitation is important to life on Earth. It is a predominant process in the global hydrologic cycle and is an indispensable component of water balance analysis. However, in some area like the Tonle Sap basin in Cambodia, the information on precipitation is deficient and sometimes difficult to access. In this case, satellite remote sensing coupled with GIS techniques have been applied and considered as a powerful and effective tool in handing precipitation analysis tasks. Recently, the Google Earth Engine (GEE) platform provides satellite datasets and collection of the tool for analysis of data using JavaScript without downloading huge data from the Internet. In this study, we aimed to evaluate the application of GEE platform for retrieving and analyzing precipitation data of the Tropical Rainfall Measuring Mission (TRMM) in Tonle Sap basin (TLS). The methods included: (1) to collect the satellite precipitation data (3B43V7) by manual download and by retrieving them from GEE platform; (2) to analyze monthly precipitation over the study area by GIS analysis functions and by JavaScript on the GEE platform, data in 2010 was sampling as a case study; and (3) to compare results from both GIS and GEE with observation data from ground stations. The results showed the good correlations between the precipitations from manual download and those from a GEE platform, with R greater than 0.9. In short, the application of GEE platform is very effective; it provides a comprehensive tool for managing time-consuming tasks, like precipitation data collection and analysis, and results in reliable outputs.

## Introduction

Precipitation is a critical variable in the global hydrologic cycle, and it influences our daily lives (drought, floods, agricultural, irrigation, outdoor activities, etc.)[1]. However, the accessibility of precipitation data in the Tonle Sap Lake region is one of limitations to conduct a comprehensive hydrological analysis.

In this case, the techniques of satellite remote sensing have been widely used and been considered as a powerful and effective tool in perceiving precipitation. However, a massive datasets have to be downloaded; satellite image processing with geographic information system (GIS) analysis function is the prerequisite before retrieval ofrainfall information.

Recently, the Google Earth Engine (GEE) leverages cloud computing services to provide analysis capabilities on over 40 years of Landsat data[2], and others satellites. As a remote sensing platform, its ability to analyze global data rapidly lends itself to being an useful tool on data visualization [3]. Additionally, dataset is processing of geospatial datasets an online for rapid visualization of complex spatial analyses using the Javascript Application Programming Interface (API). This API allows us to develop a code in order to get datasets of publicly available remotely sensed imagery and other data.

This study aimed to apply the GEE platform for automatically retrieving and analyzing precipitation data of the Tropical Rainfall Measuring Mission (TRMM) in Tonle Sap Lake basin (TLS), Cambodia. The methods included: (1) to collect the monthly precipitation data (3B43V7) by manually download and to retrieve from GEE platform; and (2) to compare a selected precipitation data of whole TLS basin in 2010, derived by GIS analysis functions and by JavaScript on a GEE platform, and (3) to compare both GIS and GEE with observation data from ground stations.

## Material and Method

## A. Study Area

The Tonle Sap Lakeis the largest permanent freshwater lake, locating in Cambodia at the Lower Mekong River basin [4]. During the dry season, the lake is about 120 km long and 35 km widewith an area of about $2500 \mathrm{~km}^{2}$. A bathymetrical survey of the lake

THA 2019 International Conference on
"Water Management and Climate Change towards Asia's Water-Energy-Food Nexus and SDGs"
23-25 January 2019, Bangkok, Thailand.
proper, conducted between 1997 and 1999, revealed a relatively flat bottom, with a maximum depth of about $3.3 \mathrm{~m}[5]$. During the flood period the Lakeexpands to 250 km long and 100 km wide with an area of about $17,500 \mathrm{~km}^{2}$, and the depth reaches $8-10 \mathrm{~m}$. The floodplain surrounding the lake extends $20-40 \mathrm{~km}$ and is dominated by seasonally inundated forest and rice field [5, 6]. The Tonle Sap basin, extends over $44 \%$ of Cambodia's total area $80,000 \mathrm{~km}^{2} .32 \%$ of Cambodia's total populationdepend on this lake in living [7].

There arefiveprovinces bordering Tonle Sap Lake namely: Siem Reap, Battambang, Pusat, Kampong Cham, and Kampong Thom. Tonle Sap Basin consists of 11 sub-basins: namely (1) Stung Sreng, (2) Stung Chikreng, (3) Tonle Sap, (4) Stung Pursat, (5) Stung Dauntri, (6) Stung Boribo, (7) Stung Sangker, (8) Stung Monkong Borey, (9) Stung Staung, (10) Stung Sen, (11) Stung Chinit and (12) Stung Sieamreap (Fig. 1).

Tonle Sap basin climate influences from the tropical monsoon seasons. Dry season runs from December to April and rainy season comes when the winds shift into the southwestmonsoonfrom May to November. The monsoon returns south during August and October when the rainfall is usually heavier, with the highestrainfall in October.

## B. Satellite Precipitation-TRMM 3B43V7

Many studies have been conducted on detecting diurnal cycles of precipitation over different parts of the world usingsatellite data, especially the Tropical Rainfall Measuring Mission (TRMM)[8].

Recently, data 3B43 is monthly executed to produce the precipitation rate field (3B43). These were combining the 3-hourly merged high-quality/IR estimates (3B42) with the monthly accumulated Global Precipitation Climatology Centre (GPCC) rain gauge analysis. Data are available from 1998 to presentat https://pmm.nasa.gov/data-access/downloads/trmm.

## C. Precipitation Processing by GEE Platform

Google Earth Engine (GEE)platform facilitates a fast analysis by using Google's cloudcomputing
infrastructure(https://earthengine.google.org). The preprocessed monthly data of Tropical Rainfall Measuring Mission data, or TRMM3B43V7, available through GEE was used to assess precipitation data across the study area. The spatial resolution of the above datasets are all equal to $0.25^{\circ} \times 0.25^{\circ}$ with monthly gridded rainfall data $[9,10]$.

This process is using JavaScript coding in GEE platform screen. TRMM 3B43V7 datasets could be specified location of boundary of Tonle Sap basins in coding. At the end, the amount of precipitation data had retrieved each sub-basins in CSV which can open with MS Excel to interpret data in number.

## D. Thiessen Polygon Method

The Thiessen polygon methodallows for areal weighting of rainfall from each gauge. $A_{i}$ is polygon area, $\mathrm{P}_{\mathrm{i}}$ is average precipitation and A is total area [11].

Fig. 1. Boundary of Tonle Sap Basin and location raingauge stations

"Water Management and Climate Change towards Asia's Water-Energy-Food Nexus and SDGs" 23-25 January 2019, Bangkok, Thailand.

## E. Statistical Indicators

Correlation coefficient (r) is measured on a scale between -1 and +1 to determine the extent to which two sets of paired values are related in a linear fashion. The number closer to -1 and +1 are -1 is a perfect negative linear correlation, whereas the number closer to +1 is a perfect positive linear correlation, and 0 is no correlation.

$$
\begin{equation*}
r=\frac{\sum_{j=1}^{N}\left(X_{j}-\bar{X}\right)\left(Y_{j}-\bar{Y}\right)}{\sqrt{\sum_{j=1}^{N}\left(X_{j}-\bar{X}\right)^{2} \sum_{j=1}^{N}\left(Y_{j}-\bar{Y}\right)^{2}}} \tag{2}
\end{equation*}
$$

Root mean square error (RMSE) is the square root of the mean of the summation of squared differences between two sets of values where there are n number of paired values x and y . This statistic provides an absolute (neither positive nor negative) value of differences between two sets of values. A smaller value signifies less error.

$$
\begin{equation*}
R M S E=\sqrt{\frac{1}{N} \sum_{j-1}^{N}\left(x_{j}-y_{j}\right)^{2}} \tag{3}
\end{equation*}
$$

## F. Methodology

In this study, 94 rainfall stations from Mekong River Commission (MRC) and Cambodia's Ministry of WaterResources and Meteorology (MoWRAM) were selected which covered almost the entire of Tonle Sap basin.

To achieve the research objectives, data processing methods were divided into three main parts (Fig. 2), including manual data acquisition and GIS processing, GEE-based data processing and gauge observation using Thiessen Polygon method.

The first part is to download monthly precipitation in 2010 (TRMM 3B43v7) in raster format (HDF), and use GIS analysis functions to interpret data, change coordinate system to the same area. Using the function "Zonal statistic as table" in order to get the amount of precipitation with "shape file of boundary".

The second part is to develop the JavaScript code on the GEE platform (https://code.earthengine.google.com).The code included: importing the TRMM image dataset; specifying the boundary of study area by uploading shape file into GEE data script; extracting the mean monthly precipitation of the basin by writing code on script (see example in Fig. 3). After having execute the code, the precipitation data were retrieved on subbasins automatically.

Lastly, the areal precipitation from gauge station were estimated by Thiessen Polygon method.

Precipitation of basin was summarized using "Zonal statistic as table" with boundary of basin. The precipitation data retrieved from the first and second methods were finally compared with the observed data from gauge stations for the entire basin and each subbasin. Statistical indicators, correlation coefficient (r) and RMSE, were estimated.

Fig. 2. Research framework

## Results and discussions

A. Monthly Precipitaion Depth

Fig. 4 shows monthly precipitation of the Tonle Sap Basin in 2010, derived from 3 methods: GIS analysis of downloaded TRMM data (GIS), GEE processing (GEE) and observed rainfall with Thiessen Polygon estimation (OBS).

1) TRMM Precipitation from GIS vs. GEE Processings
The amount of precipitation from TRMM 3B43V7 using both GIS analysis of downloaded data (GIS) and Google Earth Engine processing (GEE) methods were well matched with almost identical rainfall depths from January to December on 2010. In dry season from November to April, rainfall varied from 8 to 70 mm , while in wet season from May to October, rainfall varied from 100 to 300 mm . The highest precipitation can be observed in October around 300 mm . GEE provided an almost similar the amount of rainfall compared to manually download rainfall. There are somewhat difference between 0.005 to 1.8 mm due to round-off errors during data processing.
2) Precipitation from GEE Processings vs. Observation
From Fig. 4, TRMM precipitation from GEE processing and basin rainfall estimation from gauge

THA 2019 International Conference on
"Water Management and Climate Change towards Asia's Water-Energy-Food Nexus and SDGs" 23-25 January 2019, Bangkok, Thailand.
station (OBS) were well captured the amount of monthly rainfall. By comparing GEE rainfall with rain gauge data, we can observed an over-estimated rainfall by GEE mostly during dry period from January to June ( 4 to 20 mm ), in October and in December. Rainfall by GEE were under-estimated during wet period from July to September 30 to 49 mm . However, these values were observed as less error between rainfall from GEE and observation. Fig. 5 showed the spatial data on the monthly average rainfall in millimeters from the GEE platform.
3) Precipitation from GIS Processing vs. Observation
Based on result shown in Fig.4, the differences of rainfall depths between GIS processing (GIS) and the gauged observation (OBS) are comparable to those between GEE and OBS. The identical months of over- or under-estimation were observed. The GIS rainfall were over-estimated from the lowest of 4 mm on December to the highest of 20 mm on June.

## B. Statistical Indicators

Statistical indicators of the whole basin were shown in Table I, the amount of precipitations from manual download and those from a GEE platform provided an almost similar monthly rainfall depth with
r greater than 0.99 whole basin. Finally, both methods GEE and GIS provided a good correlation with the gauge which showed the r value greater than 0.97 and the highest RMSE of basin about 16 mm

Statistical indicators of each sub-basins were presented in Table II, the indicators demonstrated the good correlations of rainfall between GIS vs. GEE, GEE vs. observation, and GIS $v s$. observation. The correlation coefficient, r , are $0.99,0.81$ and 0.80 respectively.

Table I. Statistical Indicators of Basin

| Method | $\boldsymbol{r}$ | RMSE |
| :--- | :--- | :--- |
| GIS vs. GEE | 0.999 | 0.70 |
| GEE vs. OBS | 0.975 | 16.40 |
| GIS vs. OBS | 0.977 | 15.88 |

Table II. Statistical Indicator of each Sub-basins

| Sub basin | GIS vs. GEE |  | GIS vs. OBS |  | GEE vs. OBS |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $r$ | RMSE | $r$ | RMSE | $r$ | RMSE |
| 1 | 0.9898 | 1.20 | 0.8713 | 23.56 | 0.8818 | 23.97 |
| 2 | 0.9997 | 1.13 | 0.8719 | 27.21 | 0.8259 | 27.73 |
| 3 | 0.9998 | 1.73 | 0.9611 | 17.72 | 0.9347 | 17.94 |
| 4 | 0.9998 | 2.15 | 0.9723 | 24.81 | 0.9424 | 25.80 |
| 5 | 0.9905 | 1.39 | 0.8437 | 23.49 | 0.8824 | 23.62 |
| 6 | 0.9996 | 2.36 | 0.8089 | 20.73 | 0.8984 | 21.46 |
| 7 | 0.9991 | 2.36 | 0.9032 | 39.27 | 0.8010 | 38.77 |
| 8 | 0.9997 | 7.26 | 0.8864 | 29.70 | 0.8725 | 26.18 |
| 9 | 0.9997 | 0.86 | 0.9392 | 19.51 | 0.9697 | 19.82 |
| 10 | 0.9994 | 1.30 | 0.9393 | 19.99 | 0.9638 | 20.14 |
| 11 | 0.9997 | 1.00 | 0.8326 | 24.96 | 0.8757 | 24.64 |
| 12 | 0.9997 | 6.59 | 0.8872 | 28.41 | 0.8897 | 27.9 |

## Conclusions

Both precipitations from manually download and those froma GEE platform provided an almost similar rainfall depth for each sub-basins and the entire basin. However, the amount of precipitation of each sub-basins had some error because of uncertainty and location of the gauges in basins. TRMM 3B43V7 dataset provided high correlation when compared with the gauge stations. In short, the GEE platform is an effective tool which provides a comprehensive for managing time-consuming tasks, namely precipitation data collection and analysis. It is a new concept of remote sensing platform on how to get satellite datasets easily and quickly with results in reliable outputs.

## Acknowledgment

This paper was supported by the Kasetsart University Scholarships for ASEAN for Commemoration of the 60th Birthday Anniversary of Professor Dr. Her Royal Highness Princess Chulabhorn Mahidol. Moreover, the authors would also like to express their gratitude to the Google Earth Engine (GEE) developers for providing a registration during this research on retrieval datasets.
